

DEVICE FOR THE PROTECTION OF THE BODYWORK OF A VEHICLE.

The invention is about a device for protecting a motor vehicle bodywork, suitable in particular to be externally applied on said motor vehicle to obtain its covering.

- 5 This allows to protect the motor vehicle from harmful weather phenomena, such as violent precipitations and sunrays in the summer period, and harsh and intense cold in winter, which leads to ice formation on the bodywork, the windshield and the rear window.

Even the protection from pollutant agents, like smog, harmful for the motor vehicle bodywork or paint, is achieved.

10 As is well-known in the state of the art, to protect a motor vehicle bodywork from very dangerous weather phenomena, like for example hail or sunrays during the hottest months of the year, or from aggressive pollutant agents, like the smog produced in large industrial areas, the motor vehicle is sheltered in a garage, consisting for instance of a room belonging to a house building or a prefabricated lockup, or under a carport, for example in a workplace parking.

15 However, it often happens that the user is unable to park the motor vehicle sheltered from bad weather, especially if he lives in a town-centre, where covered stalls near his own home are insufficient, or if the company in which he works does not have a covered parking.

20 Said situation also occurs in those cases in which the user leaves his own car parked in a public parking for a lot of time.

In all the aforementioned situations, the motor vehicle can be protected only having at disposal just an ordinary cloth that, in case of an unexpected violent precipitation, like a hailstorm, is laid on the motor vehicle.

25 This is obviously a makeshift solution, which furthermore causes a not very pleasant aesthetical impact, and consequently it is not often carried out.

On the other hand, panels with a bellows structure are available, allowing to protect from sunrays, especially in the hot season, at least the motor vehicle dashboard.

30 However, these panels can be arranged inside the car only, between the inner surface of the windshield and the dashboard, and they leave said car without protection with respect to the aforementioned weather phenomena and pollutant agents.

35 For the previously mentioned reasons, it is thus evident that the motor vehicle

- 2 -

is often at the mercy of even unpredictable weather phenomena and pollutant agents, with all the inconveniences involved.

Document WO 94/25303 shows a device for protecting a motor vehicle bodywork, provided with a container housing a roller therein, around which a cloth used to cover the motor vehicle is wound.

The aforementioned protection device has some limitations.

The first limitation is due to the fact that it is not provided with a practical cloth cleaning system.

This cleaning is essential, because weather phenomena, dust or pollutant agents cause the worsening of the cloth upper surface cleaning condition.

Moreover, in the prior art, and in particular in the cited known technique closest to the invention hereby described, it is not evidenced the fact that the cloth, when it covers the motor vehicle bodywork, is usable as a support surface of graphic symbols well visible for the persons, having advertising purposes, of identification or decoration.

The present invention intends to overcome the aforementioned inconveniences.

In particular, it is the main object of the invention to provide for a motor vehicle bodywork protection device which allows to clean the cloth, without requiring the user's intervention, during the opening and closing stages of said cloth.

It is a second object of the invention to provide for an easy to manufacture motor vehicle bodywork protection device.

It is another object to provide for a protective device which is rapidly and easily applicable by any motor vehicle user.

It is an object of the invention too to provide for a motor vehicle protective device which is suitable to be used against critical weather phenomena in any season and against different pollutant agents.

Not the least object is that of providing a device which, besides protecting a motor vehicle bodywork, is usable at the same time for advertising purposes, of identification or decoration, without requiring the use of substantially steady means such as self-adhesive stickers, colour spraying, cuttings or the like, used nowadays for associating advertising graphic symbols with the motor vehicle.

Said objects are obtained by a device for protecting a motor vehicle bodywork which, according to the content of the main claim, comprises:

- 3 -

- at least a flexible laminar element, able to be laid out to cover said motor vehicle;
- at least a mainly longitudinal developed housing structure, able to contain said laminar element when it is in inoperative conditions, provided with:
 - 5 - connection means to said motor vehicle;
 - at least a longitudinal slot for the passage of said laminar element from the interior to the outside of said housing structure, and vice versa;
 - handling means, coupled with said laminar element and available to the user, to extract said laminar element from said housing structure and to
 - 10 dispose it to cover said motor vehicle;
 - hooking means, coupled with said handling means, able to connect said laid out laminar element to said motor vehicle,

which is characterized in that it comprises cleaning means, coupled with said housing structure at said longitudinal slot, able to remove the impurities from

15 said laminar element during its movement.

It is also an object of the present invention a flexible and winding surface comprising one or more writings, drawings, types, symbols, distinctive signs, logos and the like which, according with the related main claim, is characterized in that it consists of at least a laminar element belonging to the

20 device according to claim 1.

Advantageously, the device of the invention is easy to manufacture and it is practically and easily applicable to the motor vehicle by any user.

More advantageously, the invention allows the vehicle's owner to externally protect his motor vehicle bodywork or paint from any harmful weather

25 phenomenon or pollutant agent.

Still advantageously, the device of the invention is extremely easily portable because, in inoperative conditions, it has reduced encumbrance and weight with respect to the above described prior art.

Moreover, it can be arranged in a very easy way, for instance in the motor vehicle's boot, being always at the user's disposal, who can thus utilize it at

30 any time and in any place, even in case a sudden intense precipitation, such as a hailstorm, arises.

Furthermore, the invention makes available a new means for advertising purposes, of identification or decoration, consisting of a cloth belonging to a

35 housing structure removably coupled with the motor vehicle bodywork.

- 4 -

The aforesaid objects and advantages will be better highlighted in the description of preferred embodiments of the invention, given in an explanatory way, with reference to the figures of the annexed drawings, wherein:

- Figure 1 is an axonometric view of a motor vehicle provided with the device of the invention;
- Figure 2 is an axonometric view of an enlarged detail of Figure 1, with the device of the invention in inoperative conditions;
- Figure 3 is a cross sectional view of the device of Figure 2;
- Figure 4 is a partial sectional axonometric view of the device of Figure 2;
- Figure 4a is an axonometric view of an enlarged detail of Figure 4;
- Figure 5 is an axonometric view of the device of Figure 2, in closing conditions;
- Figure 6 is an axonometric view of a different executive embodiment of the device of Figure 2;
- Figure 7 is a side view of the device of Figure 6;
- Figure 8 is an axonometric view of a first executive embodiment of the device of Figure 2;
- Figure 9 is an axonometric view of a second executive embodiment of the device of Figure 2;
- Figures from 9 to 13 are axonometric views of different executive embodiments of the device of the invention;
- Figure 14 is a side view of another executive embodiment of the device of the invention; and
- Figures 15 and 16 are top views of further executive embodiments of the device of the invention.

The device of the invention is shown in operative conditions in Figure 1, where it is generally indicated with numeral 1, disposed to protect the bodywork **C** of a motor vehicle, generally indicated with **A₁**.

As one can see, the device 1 comprises two flexible laminar elements, generally indicated with numerals 2 and 3, which are laid out to cover the motor vehicle **A₁**.

In particular, the laminar element 2 covers the front portion, while the laminar element 3 covers the rear portion of the motor vehicle **A₁**.

The device 1 comprises a mainly longitudinal developed housing structure, generally indicated with numeral 4, which contains the laminar elements 2, 3

- 5 -

when they are in inoperative conditions.

Said housing structure **4** is provided with:

- connection means, generally indicated with numeral **5**, to the motor vehicle **A₁**;
- 5 - two longitudinal slots, of which only one, indicated with numeral **9**, is shown, allowing the passage of the laminar elements **2, 3** from the interior to the outside of the housing structure **4**, and vice versa.

It is pointed out that the laminar element **2** passes through the longitudinal slot **9**.

- 10 The device **1** therefore comprises handling means, generally indicated with numeral **6**, coupled with the laminar elements **2, 3** and available to the user, for instance the owner of the motor vehicle **A₁**.

The handling means **6** are operated to extract the laminar elements **2, 3** from opposite sides of the housing structure **4**, and to dispose them to cover the motor vehicle **A₁** in the manner shown in Figure 1.

15 As evidenced in the same Figure, the device **1** further comprises hooking means, generally indicated with numeral **7**, coupled with the handling means **6**, joining the two laminar elements **2, 3** to the motor vehicle **A₁** when they are fully laid out.

- 20 More particularly, the Figure 2 shows that the handling means **6** consist of a tubular element **28**, coupled with the free end **2a** of the laminar element **2** and internally provided with an elastic wire **29**, to whose ends **29a, 29b** the hooking means **7** are applied, consisting in their turn of hooks **32, 33** which, as visible in Figure 1, are joined to the wheelhouses **R** when the laminar element **2** has to be positioned to cover the front portion of the motor vehicle **A₁**.

25 What previously explained for the laminar element **2** is also applicable for the laminar element **3**, which protects the rear portion of the motor vehicle **A₁** and whose handling means **6**, visible in Figure 3, consist of the tubular element **30** internally provided with the elastic wire **31**, while the hooking means **7**, for exposition simplicity, are not shown in the subsequent Figures.

30 In further executive embodiments, the hooking means could be of different kind, for example magnetic elements to be positioned near the motor vehicle bodywork to maintain stretched the laminar element.

Concerning the housing structure **4**, the Figure 2 shows that it consists of a shell **8** having a cross sectional profile of essentially elliptic shape, to avoid

35

- 6 -

dust or impurities of other kind to deposit on the outer surface **4a** of the housing structure **4**.

In Figure 3 said constructive shape of the shell **8** is better highlighted, composed by two half-shells **81**, **82** obtained by laminated aluminium extrusion and disposed side by side at the longitudinal symmetry axis **Z** of the housing structure **4**.

According to other constructive embodiments of the invention, the shell could be made of PVC or carbon fibre, just to mention some of the materials preferably usable for this component.

With reference to the laminar elements **2**, **3**, Figures 2 and 3 show that each of them has an end fixed to a support element, generally indicated with numerals **10**, **11**, disposed inside the housing structure **4**, and developed according to the longitudinal symmetry axis **Z** of the housing structure **4** for a length substantially equal to the length of the longitudinal slot previously indicated with numeral **9**.

In this specific case, the support element **10**, **11** consists of a winding cylinder **12**, **13** around which the respective laminar element **2**, **3** is wound or unwound during the release operation from the covering position of the motor vehicle **A₁**, or the tensioning operation to the closed position.

The laminar elements **2**, **3** consist respectively of a roll-up cloth **14**, **15**, of known type for carrying out covering surfaces to protect vehicles, persons or other from weather phenomena, like for instance high intensity sunrays and beating rain.

Preferably, the roll-up cloth **14**, **15** has a thickness of about 1,5 mm and it is made of laminated PVC with a silver coloured polyethylene terephthalate (PET) film.

This allows the roll-up cloth **14**, **15** to resist high temperatures to the order of 80° C during the hottest seasons, since said material has a high deflection coefficient and a low reflection degree of the sunrays.

According to the invention, the device **1** comprises cleaning means, generally indicated with numeral **25**, coupled with the housing structure **4** at the longitudinal slot of the type indicated with numeral **9**, which perform their function during the movement, that is the opening and closing, of the laminar elements **2**, **3**, removing the impurities deposited on them when they are laid out on the motor vehicle **A₁**, as shown in Figures 3 and 4 and in the

- 7 -

enlargement of Figure 4.

The cleaning means **25** are applied to a support bar **26** connected to the inner surface **4c** of the housing structure **4** through joining means, not shown but consisting, for example, of adhesive substances.

- 5 Preferably but not necessarily, the cleaning means **25** consist of a strip of woven wires **27**, soaked with silicone to minimize light passage, to resist temperature variations and to make waterproof said strip.

10 In Figures 3 and 4 one can see that the device **1** of the invention comprises elastic means, generally indicated with numeral **16**, disposed inside the housing structure **4**, which maintain in tension the laminar elements **2**, **3**.

The elastic means **16** are placed at the end **4b** of the housing structure **4**, but it is evident that, in other constructive embodiments, they could be provided at the opposite end of said structure too.

15 In Figure 4 it is shown that the housing structure **4** is provided with a pair of shaped brackets, of which only one, indicated with numeral **17**, is visible, each laterally coupled with the housing structure **4** through joining means of known type, not shown hereby, for example screws.

20 As one can see in the subsequent Figure 5, but also in Figure 2, each of the aforementioned shaped brackets is externally provided with a cap **18**, **19**, made of PVC, which is disposed to laterally cover the housing structure **4** for giving it a homogeneous aesthetical aspect.

According to the preferred executive embodiment hereby described, the connection means **5**, shown in section in Figure 3 and in axonometric view in Figures 4 and 5, comprise a pair of magnets **20**, **21**, coupled with the roof **T₁** of the motor vehicle **A₁** and joined through first fixing means, generally indicated with numeral **22**, to the outer surface **4a** of the housing structure **4**.

25 The first fixing means **22** are composed by screws (not shown in the drawings) that couple in a rigid manner the magnets **20**, **21** with bearing elements **23**, **24** of the housing structure **4**, disposed side by side and substantially **U** shaped, with their lateral ends longer than the central ends brought near to define a concave surface which is adapted to the convexity of the outer surface **4a** of the housing structure **4**.

30 In Figure 6 another executive embodiment of the invention is shown, in which the device, now generally indicated with numeral **100**, differs from that described with reference to Figures from 1 to 5 because the connection

35

means, generally indicated with numeral **103**, comprise two flexible belts **104**, **105**, preferably made of rubber, coupled with the housing structure, generally indicated with numeral **102**, and joined in a stable but removable way to the upper post **M₂** of the respective door **P₂** of the motor vehicle **A₂**.

5 The connection means **103** also comprise a pair of bearing pads **106**, **107**, preferably made of rubber, coupled with the roof **T₂** of the motor vehicle **A₂**, upon which the outer surface **102a** of the housing structure **102** is disposed.

Figure 7 highlights the flexible belt **104** and its connection to the housing structure **102**, made stable by the application of the shaped bracket **108** to said housing structure **102** through the joining means **109**, consisting for
10 example of screws.

Preferably but not necessarily, the laminar element **101**, illustrated in inoperative conditions in Figure 6, consists of a PTC (acronym of "Positive Temperature Coefficient material") or aluminium sheet, and it is thus suitable
15 for being used in winter season to protect the motor vehicle **A₂** from ice.

In this case, the laminar element **101** is provided with a heating system (not shown in the drawings) of known type, consisting for instance of a metallic frame of small pipes containing antifreeze fluid.

The heating system is coupled with feeding means (not shown in the drawings
20 too) preferably consisting of a rechargeable battery.

The heating fluid could be activated both by pushing a button from the interior of the motor vehicle **A₂** and by using a remote control.

Figure 8 shows a further executive embodiment of the invention, in which the device, generally indicated with numeral **200**, still differs from the already
25 described ones for the connection means, generally indicated with numeral **203**.

In this case, they comprise a hollow body **204**, connected through second fixing means, not shown in the drawings but consisting of screws again, to the outer surface **202a** of the housing structure, generally indicated with numeral
30 **202**, to define a space **205** in which two shaped bars are inserted from opposite sides, of which only one, indicated with numeral **206**, is visible in Figure 8.

Each shaped bar has an end, indicated with numeral **206a** for the shaped bar **206**, rigidly fixed to the respective vertical post **M₃** of the motor vehicle **A₃**,
35 carrying out in this way a stable and almost not removable coupling of the

- 9 -

device **200**, differently from the devices **1** and **100** which are coupled in an easily removable way to the respective motor vehicle **A₁**, **A₂**.

At last, in Figure 9 another executive embodiment of the invention is shown, in which the device, generally indicated with numeral **300**, differs from the previously described ones in that each of the laminar elements, generally indicated with numerals **301** and **302** respectively, consists of a pliant cloth **305**, **306** respectively, with bellows configuration.

According to the preferred executive embodiment hereby described, the support element, indicated with numeral **304**, consists of the inner surface **303c** of the housing structure, generally indicated with numeral **303**, to which the laminar elements **301**, **302** are connected according to known methods.

Operatively, the user applies the device **1** of Figure 1 on the motor vehicle **A₁**, by anchoring the magnets **20**, **21**, previously fixed to the housing structure **4**, on the roof **T₁**.

In inoperative conditions, the device **1** appears as it is shown in Figure 5, with the hooks **32**, **33** mutually coupled at the middle zone of the housing structure **4**.

In case of critical weather conditions, like beating sun, the user releases the hooks **32**, **33** from their mutual coupling, grasps the tubular element **28** and exerts on it a traction, until the laminar element **2** is disposed to cover the front portion of the bodywork **C** of the motor vehicle **A₁**.

Once the laminar element **2** is unwound from the winding cylinder **12** for its entire length, the user fastens it in the reached position, by engaging the hooks **32**, **33** with the wheelhouses **R** of the motor vehicle **A₁**.

It similarly happens for the laminar element **3**, which is disposed to cover the rear part of the motor vehicle **A₁**, and it is maintained stable thereby by engaging the hooking means with the rear wheelhouses **R**.

In such situations, the device **1** is able to protect the bodywork **C** of the motor vehicle **A₁**, granting its outer integrity, from the sunrays action, or even from other harmful weather phenomena, like for instance the hail, very frequent in the summer period too.

When the protection of the motor vehicle **A₁** is no more necessary, the user disengages the hooks **32**, **33** from the wheelhouses **R** and, by releasing the grasp on the tubular element **28**, he allows the elastic means **16** to draw back the laminar elements **2**, **3** inside the housing structure **4**.

- 10 -

When he wishes to perform an accurate cleaning of the laminar elements **2, 3**, the user holds the tubular element **28** and accompanies their winding movement, opposing the drawback force of the elastic means **16**, so that the cleaning means **25** remove the impurities from the cloths **14, 15**.

5 In case of the device **100** of Figure 6, the user, after leaning the housing structure **102** on the bearing pads **106, 107**, couples the belts **104, 105** internally to the upper posts **M₂** of the respective door **P₂** of the motor vehicle **A₂** so that, when the door **P₂** is closed, the device **100** is sufficiently fastened to the motor vehicle **A₂**.

10 This constructive solution is appropriate when the device **100** has to be applied with great quickness, especially in urgent situations like the unexpected arrival of a summer storm, with the motor vehicle **A₂** parked in a public parking.

On the contrary, the embodiment of Figure 8 is more suitable for those cases in which the device **200** has to be definitely mounted on the motor vehicle **A₃**,
15 by using fixing means of known type like for instance screws, to fasten the device **200** to the vertical post **M₃** of motor vehicle **A₃**.

The embodiment of Figure 9 provides for the extraction of the laminar elements **301, 302** from the housing structure **303**, to dispose them for covering the motor vehicle **A₄** in the same manner with respect to what
20 described for the device **1**.

To put the laminar elements **301, 302** back inside the housing structure **303**, the user should only folding the respective cloths **306, 307** according to the bellows configuration, not being provided in this case the tensioning elastic means present in all the other embodiments.

25 Therefore, the device of the invention allows to perform the cleaning of the laminar elements in a practical and automatic way, that is whenever they are extracted or put back from/in the housing structure applied on the motor vehicle bodywork, without an actual intervention of the user.

Consequently, during the subsequent utilizations, the laminar elements
30 belonging to the device of the invention have a better cleaning condition with respect to that granted by equivalent devices of known type, with the evident advantages this involves in aesthetical terms.

The device protects in an effective way the outer part of the motor vehicle bodywork from any weather phenomenon, like hail or sunrays in summer
35 period and ice in winter period, or from the action of pollutant agents, like

- 11 -

smog.

The car protection is granted in any period of the year, in any place and with any weather condition.

Due to its reduced encumbrance, the device of the invention can be practically
5 arranged inside the car, for instance in the boot.

This allows the user to have immediately at disposal the device, and to effectively face unpleasant situations, like the unexpected arrival of a hailstorm, even when he is in not sheltered places.

The device of the invention is easily mountable on the motor vehicle,
10 preferably at the middle zone of said vehicle's roof.

However, according to other executive embodiments of the invention, shown in Figures 10 and 11, the housing structure **400** and the connection means could be respectively coupled with the bonnet **F** or with the boot **B** of the motor vehicle.

15 According to other executive embodiments, shown in Figures 12 and 13, the housing structure **500** and the related connection means could be coupled with the front bumper **U_a** and/or the rear bumper **U_p** of the motor vehicle.

In such case, the flexible laminar element will be respectively pulled toward the front part or the rear part of the motor vehicle, to be disposed to protect it, and
20 it will obviously have a proper length.

Moreover, in other embodiments, as evidenced in Figure 14, the housing structure **500** could be housed in one or more spaces **V₁**, **V₂** obtained on the motor vehicle roof.

It is still evident that, in further executive embodiments of the invention, shown
25 in Figures 15 and 16, the hooking means **7** could be joined to the front bumper **U_a** and/or the rear bumper **U_p**, or to the wing mirrors **S** of the motor vehicle, according to the protection degree to grant to said motor vehicle.

Such Figures still show another peculiarity of the invention hereby described which concerns, as previously mentioned, even a flexible and winding surface
30 comprising writings, drawings, types, symbols, distinctive signs, logos and the like, indicated with **D**, used for advertising purposes.

The flexible surface consists of the flexible laminar elements **2**, **3** placed inside the housing structure **4** coupled with the bodywork **C** of the motor vehicle **A₁**, laid out to cover said bodywork **C**.

35 Obviously, on the outer surface of the flexible laminar elements, but also of the

housing structure, any types, drawings, writings, distinctive signs or logos, both with advertising and identification purpose, could be printed, like for example the number plate of the own car, or with decorative purpose, with drawings photographs or special colours.

5 It is immediately evident the advantage produced by the use of at least one of the cloth of the device of the invention, for instance as advertising surface. In fact, in this case, a payment to the user of the device by the company owner of the advertisements could be provided.

Otherwise, the device could be freely provided by the supplier of the
10 advertisements.

On the basis of the aforesaid description, it should be understood that the device for protecting a motor vehicle bodywork according to the invention achieves all the objects and attains all the previously mentioned advantages. Modifications to the device of the invention could be introduced in the
15 productive stage, by providing for instance for a single cloth, coupled with the housing structure, to cover the motor vehicle, as one can see in Figures from 10 to 14.

In other executive embodiments, the device of the invention could comprise a different number of housing structures, for instance two.

20 Moreover, both the flexible laminar element and the housing structure could be made of any colour, allowing the producer to differentiate and change at his will the aesthetical aspects.

For example, the colour of the device could be combined with the colour of the motor vehicle bodywork, to give a pleasant general aesthetical impact

25 The device of the invention could be manufactured in several sizes, to allow its application on different motor vehicle models.

Furthermore, in other constructive embodiments, the housing structure shape could be different from the previously described one, without reducing the advantage provided by the present patent.

30 All the described and cited embodiments, even if not shown in the annexed drawings, when they should fall within the scope of protection of the following claims, should be considered protected by the present patent.
